Today

- Random number streams
- Modeling workflow
- Bernoulli distribution for binary events
- Agent-based models

Modeling workflow: bio model

- Think about **biological processes** at the level of interacting "units" or "**agents**"
 - population ecology: individuals
 - physiology: cells or organelles
 - biochemistry: molecules
 - ecosystem ecology: individuals & molecules

Modeling workflow: bio model

- Think about **biological processes** at the level of interacting "units" or "**agents**"
- Make stochastic models for **small pieces**
 - stochastic model for death due to getting eaten by a predator
 - stochastic model for death due to competition or conflict with others
 - stochastic model for death due to other random events
 - stochastic model for birth
 - stochastic model for dispersal

Modeling workflow: bio model

- Think about **biological processes** at the level of interacting "units" or "**agents**"
- Make stochastic models for **small pieces**
- **Simulate** the pieces to confirm intuition and correctness
 - check against known results ("unit tests")

Modeling workflow: bio model

- Think about **biological processes** at the level of interacting "units" or "**agents**"
- Make stochastic models for **small pieces**
- **Simulate** the pieces to confirm intuition and correctness
- Put the pieces **together** to make a model of the system
 - check against known results ("unit tests")

Modeling workflow: bio model

- Think about **biological processes** at the level of interacting "units" or "**agents**"
- Make stochastic models for **small pieces**
- **Simulate** the pieces to confirm intuition and correctness
- Put the pieces **together** to make a model of the system
- **Simulate** the system
 - check against known results

Modeling workflow: bio model

- Think about **biological processes** at the level of interacting "units" or "**agents**"
- Make stochastic models for **small pieces**
- **Simulate** the pieces to confirm intuition and correctness
- Put the pieces **together** to make a model of the system
- **Simulate** the system
- Derive higher-level simplified models by **scaling up** check scaled-up model against ABM

Random number streams

- Keep track of the state of the RNG
- Feed back in to the iterative algorithm
- Continue using the same stream
- Each successive number is deterministic
 - repeatable, reproducible
- No need to set a new seed each time we want the next set of random numbers

Binary stochastic events

- Conceptualize a **biological process** as an **event** that occurs with **probability p**
 - death, disturbance, mutation, move ...
- Two outcomes (binary)
 - event occurs
 - event doesn't occur (or different event)
- Probability **represents uncertainty** about which outcome occurs

Binary stochastic events

- Conceptualize a **biological process** as an **event** that occurs with **probability p**
 - death, disturbance, mutation, move ...
- Two outcomes (binary)
 - event occurs
 - event doesn't occur (or different event)
- Probability **represents uncertainty** about which outcome occurs

This is the abstraction step: a model for the stochastic process

These assumptions $\longrightarrow$ **Bernoulli** distribution

Bernoulli RNG algorithm

Builds on uniform
random numbers

Algorithm

generate a random number U from $U(0,1)$

if $U \leq p$

 event occurs

else

 event doesn't occur (or other event occurs)

Bernoulli distribution

- Probability of a binary event

- $\Pr(X=1) = p$

Random variable
(our abstract concept)

- $\Pr(X=0) = 1 - p$

$$f(x; p) = \begin{cases} p & \text{if } x = 1 \\ 1 - p & \text{if } x = 0 \end{cases}$$

Probability
mass
function
(pmf)

$$X \sim \text{Bernoulli}(p)$$

Agent-based models

- Biological processes from the perspective of **agents**
 - typically individuals in ecology/evolution
 - ... hence “individual based model” IBM
 - species, genes, nucleotide locations, molecules

Agent-based models

- Biological processes from the perspective of **agents**
- Processes are carried out or experienced by agents
 - predation: one agent eats another
 - death: the agent dies
 - birth: one agent produces new agents
 - dispersal: an agent moves from one location to another

Agent-based models

- Biological processes from the perspective of **agents**
- Processes are carried out or experienced by agents
- **Explicitly track** each agent/individual

Agent-based models

- Biological processes from the perspective of **agents**
- Processes are carried out or experienced by agents
- **Explicitly track** each agent/individual
- Agents/individuals have **attributes/properties/traits**
 - alive/dead
 - location
 - age
 - size

Agent-based model

- 100 individuals, $p_{\text{death}}=0.2$ in 1 year

Algorithm

set each individual to “alive”

set each individual to $p_{\text{death}} = 0.2$

for each individual

 generate U from $U(0,1)$

 if $U \leq p_{\text{death}}$

 set individual to “dead”
